Influence of age on Doppler echocardiographic indices of left ventricular diastolic function

Sir,
We read with interest Spirito and Maron's article (1988;59:672–9). Their conclusions about the effect of aging on diastolic left ventricular filling accord with ours.\(^1\) We showed that atrial filling fractions increased significantly with age in normal subjects from 12\% to 46\%, and we concluded that "age-corrected nomograms are mandatory in assessing atrial filling fraction in individual patients". We also found, as did others,\(^2\) that mitral regurgitation can augment early diastolic filling and alter the left ventricular filling pattern. Even slight mitral regurgitation can influence the inflow pattern and can lead to apparent normalisation of early diastolic filling in patients with disturbed diastolic function. This implies that when Doppler echocardiography is used to study left ventricular filling, mitral regurgitation should be taken into account, especially as it can be clinically silent.
