Table 1 Clinical characteristics

Risk factor	LBBB (n=155)	STEMI (n=1720)	p Value
Mean age ($\pm$ SD)	70.35 $\pm$ 11.9	64.95 $\pm$ 14.0	<0.0001
Male	87 (56.1%)	1228 (71.4%)	<0.0001
Hypertension	70 (45.2%)	668 (38.8%)	0.127
Hypercholesterolaemia	52 (33.5%)	512 (29.8%)	0.327
Diabetes mellitus	26 (16.8%)	201 (11.7%)	0.063
Previous MI	36 (23.2%)	205 (11.9%)	<0.0001
Previous CABG	10 (6.5%)	44 (2.6%)	0.005

Table 2 Clinical outcomes

Outcome	LBBB (n=155)	STEMI (n=1720)	p Value
Door-to-balloon time (min $\pm$ SD)	40 $\pm$ 17	37 $\pm$ 25	0.710
Call-to-balloon time (min $\pm$ SD)	128 $\pm$ 36	120 $\pm$ 47	0.263
Acute coronary occlusion	19 (12.2%)	1096 (63%)	<0.0001
PCI performed	40 (26%)	1430 (83%)	<0.0001
30-day mortality (all)	8 (5.2%)	120 (6.9%)	0.391
30-day mortality (PCI)	3/40 (7.5%)	94/1430 (6.6%)	0.825
30-day mortality (no PCI)	5/115 (4.3%)	26/290 (8.9%)	0.115
Overall mortality	32 (27.8%)	240 (13.9%)	0.023

ST-elevation myocardial infarction (STEMI) referred to our tertiary centre for PPCI.

Methods All patients accepted for PPCI within the period of September 2009 to November 2011 were included in the study. Patient data obtained from our Cardiac Services Database System (Phillips CVIS) were analysed and angiographic images reviewed on our Cardiac Image Database (McKesson Horizon). Mortality data were gathered from the Summary Care Record (SCR) database. Statistical comparisons of continuous variables were made by an unpaired t test. Categorical variables were compared using the χ^2 test. A p value of <0.05 was considered to indicate statistical significance.

Results During the study period, 1875 patients were referred for PPCI of whom 155 (8.3%) had LBBB. Compared with STEMI, patients with LBBB were significantly older, more likely to be female and have prior history of MI and CABG (table 1). Patients with LBBB had similar door-to-balloon (DTB) and call-to-balloon (CTB) times. PCI was performed in 40 (26%) patients with LBBB

Aims Current national and international guidelines continue to recommend activation of the primary percutaneous coronary intervention (PPCI) pathway in patients presenting with chest pain and presumed new-onset left bundle branch block (LBBB). Previous research has suggested that a lower proportion of patients presenting with LBBB require emergency intervention. In this study we have compared baseline clinical characteristics, angiographic findings and subsequent outcome in patients with LBBB versus

Figure 1 Clinical outcome in patients with LBBB.

Figure 2 Kaplan-Meier comparison of survival curves.

although an acutely occluded culprit vessel was found in only 19 (12.2%) patients (table 2). Furthermore, 85 (54.8%) patients had non-flow limiting coronary artery disease and of those with significant disease 12 (7.7%) patients required CABG (figure 1). Overall, an acute coronary syndrome (defined as ischaemic chest pain with positive troponin) was confirmed in only 67 (43.2%) of patients presenting with LBBB. 30-day mortality was similar between LBBB and STEMI patients (table 2). However, during a mean follow-up period of 2.1 years, overall mortality was significantly higher in the LBBB group compared to STEMI (HR 2.01, 95% CI 1.26 to 3.20) (figure 2).

Conclusions Our study shows that, in contrast to STEMI, only a small proportion of patients presenting with chest pain and LBBB had an acutely occluded coronary artery. Although short-term mortality was similar between the two groups, long-term outcome was significantly worse in patients with LBBB. Further work is needed to identify those patients presenting with LBBB who are most likely to have an acute coronary occlusion, in order to facilitate the appropriate use of emergency coronary angiography and PPCI.
