Heartbeat: Healthcare approaches to reducing adverse outcomes in patients with atrial fibrillation

Catherine M Otto

Atrial fibrillation (AF) affects over 30 million people worldwide. The increased risk of stroke and mortality associated with AF accounts for an increasing global burden of disease, both in terms of adverse outcomes and resultant costs. In standard medical practice, adherence to guideline based preventative anticoagulation is suboptimal. An integrated care model, using a multidisciplinary team and community support to provide patient-centred care, has been proposed to improve outcomes in the AF population. In a systematic review and meta-analysis that included 1383 AF patients, Gallagher and colleagues1 found that an integrated care approach was associated with a reduction in both all-cause mortality (OR 0.51, 95% CI 0.32 to 0.80, p=0.003) and cardiovascular hospitalisations (OR 0.58, 95% CI 0.44 to 0.77, p=0.0002) (figure 1).

Also in this issue, Wong and colleagues3 examined data from almost 40 000 women, with a mean age at baseline of 50 years, to study whether menopause is associated with an increased incidence of AF. Based on 1350 AF events over 20.5 years of follow-up, oestrogen-only hormone replacement therapy was associated with an increased risk of AF (HR 1.22; 95% CI 1.02 to 1.45) but there were no significant differences based on age at menopause or use of combined hormone therapy.

In the accompanying editorial, Guhl and Magnani4 remind us that, despite this encouraging study in terms of AF risk, “Menopausal age is established as a strong marker of adverse cardiovascular risk. Earlier age of menopause has been related to increased myocardial infarction, stroke, heart failure and cardiovascular mortality” (figure 3).

The role of revascularisation versus medical therapy for older adults with non-ST-elevation acute coronary syndrome (NSTEMI) remains controversial. In a meta-analysis of four randomised trials and three observational studies that included over 20 000 patients aged 75 years or older, Gnanenthiran and colleagues5 found that a routine invasive strategy reduced the risk of death (OR 0.67, CI 0.61 to 0.74), myocardial infarction (OR 0.56, CI 0.45 to 0.70) and stroke (OR 0.53, CI 0.30 to 0.95) but resulted in a reduction in AF-related hospitalisations or cerebrovascular events.

Figure 3  The figure presents a hypothesised association between age of menopause and cardiovascular outcomes, emphasising the consistent absence of a relation to atrial fibrillation as borne out by multiple epidemiological studies.

in a greater than twofold increased risk of major bleeding (figure 4).

De Carlo and Liga6 comment that “While adequately-powered randomised controlled trials are still needed to define the most appropriate approach in elderly patients with NSTEACS, the meta-analysis by Gnanenthiran et al5 provides new, good-quality evidence supporting an early invasive strategy, which was associated with a significant reduction in most clinical hard endpoints. In this context, strategies able to limit the occurrence of bleeding complications (ie, trans-radial approach) and to better guide revascularisation (ie, invasive assessment of coronary flow reserve in the case of multivessel disease) should be implemented to maximise the clinical benefit and contain the risks of a routine invasive approach.”

A set of two review articles in this issue discuss the vexing problem of prosthetic valve thrombosis, both with surgically implanted bioprosthetic and mechanical valves7 and with transcatheter bioprosthetic valves8 (figure 5). These summaries of the current literature can help guide future clinical research on this important complication of heart valve replacement.

The Education in Heart article9 in this issue discusses cardiac resynchronisation therapy for management of heart failure with reduced ejection fraction. The pathophysiologic rationale, patient selection, and procedural technique are summarised concisely in this article. The Image Challenge10 shows an apical cyst on echocardiography and chest CT in a
