Conclusion The data show that higher levels of IgM antibodies, including IgM anti-MDA, are associated with a decreased coronary necrotic core volume and lipid core burden, whereas total serum IgG and IgG anti-MDA LDL antibodies were not related to the measured plaque characteristics. The ability of IgM antibodies but not HDL- or LDL-cholesterol levels to indicate these important plaque characteristics is consistent with a proposed mechanistic role.

Pulmonary arterial hypertension (PAH) is a chronic and life-threatening disease with high morbidity and mortality in adult and paediatric patients. PAH is characterised by a progressive narrowing and occlusion of small pulmonary arteries leading to increased pulmonary resistance, right ventricular hypertrophy, and, finally, right ventricular failure.

A large body of data has shown that proliferation and migration of pulmonary arterial smooth muscle cells (PASMCs) represent key events in the vascular remodelling of pulmonary arteries that occurs during PAH. Levels of cytoplasmic calcium are an important determinant of PASMC proliferation and migration, and failure in maintaining appropriate levels of intracellular calcium are associated with PAH. The plasma membrane calcium ATPase (PMCA) proteins extrude calcium from the cytosol to the extracellular medium, and in doing so, play a critical role in the modulation of intracellular calcium levels. In this work, we have investigated whether inducers of PAH trigger any changes in the expression of PMCA proteins in PASMCs.

Analysis of RNA expression levels for PMCA genes has revealed that treatment of PASMCs with PDGF results in a significant increase in the level of the RNA encoding for the protein PMCA1. Interestingly, PMCA1 RNA levels were also elevated in lungs of rats with monocrotaline-induced PAH. No changes were observed in the RNA levels for PMCA4, the other major PMCA isoform expressed in PASMCs. Although previous studies on the regulation of PMCA1 gene expression have identified functional binding sites for the transcription factors NFAT in the PMCA1 promoter region, we show here that PDGF-mediated upregulation of PMCA1 transcriptional expression is independent of activation of the calcineurin/NFAT signalling pathway.

Our results suggest the involvement of PMCA1 in PASMC deregulation during PAH, although determination of the link between increased expression of PMCA1 and PAH requires further investigation.

Introduction Genome wide association studies have identified Tribbles-1 (*TRIB1*) to be significantly associated with all major plasma lipid traits and as a risk factor for ischaemic heart disease and myocardial infarction. Studies in mice using *Trib1* full body KO and liver-specific over-expression and KO models have shown that hepatic expression of *TRIB1* reduces circulating lipids. Additionally, *Trib1* has been implicated as a regulator of alternatively activated macrophages. However the potential interplay between hepatocytes, macrophages and *Trib1* remain unexplored.

This study aimed to assess whether myeloid *Trib1* regulates tissue macrophage polarisation and investigate its consequences on plasma lipid homeostasis.

Methods We developed myeloid specific *Trib1* conditional knockout (*Trib1* fl/fl x *Lyz2*Cre; *Trib1*^{KO}) and over-expressor mice (*ROSA26**Trib1*.Tg x *Lyz2*Cre; *Trib1*^{Tg}), thereby deleting or over-expressing *Trib1* in myeloid cells. Plasma lipid levels were directly measured by ion mobility. Macrophage phenotype was characterised in the liver (Kupffer cells, KCs), adipose (ATMs) and BMDMs by qPCR and semi-quantitative immunofluorescence analysis. Western blotting was used to assess regulators of macrophage polarisation. Furthermore, microarray analysis of human monocyte derived macrophages (MDMs) was employed to identify potential *TRIB1*-regulated cytokines.

Results Loss of myeloid *Trib1* increased levels of plasma triglyceride, VLDL-C ($p < 0.05$) and promoted pro-inflammatory polarisation in KCs ($p < 0.01$), ATMs ($p < 0.01$) and BMDMs ($p < 0.05$), while *Trib1*^{Tg} mice revealed opposing changes in all parameters assessed. Western blotting showed *TRIB1* modulates protein levels of C/EBP- β^2 and - β^2 ($p < 0.05$), both key regulators of macrophage polarisation, via the control of COP1 activity and miR-155 expression. Microarray analysis of MDMs indicated *TRIB1* may regulate production of a number of pro-inflammatory cytokines that are implicated in fatty liver disease and adipocyte lipolysis. Reduced expression of these was confirmed in *Trib1*^{Tg} BMDMs ($p < 0.05$).

Conclusions Myeloid *Trib1* is a potent regulator of lipid homeostasis, the loss of which promotes inflammation in metabolic tissues. Our observations uncover a novel mechanism of KC-hepatocyte cross talk mediated through *Trib1*.
