cardiovascular outcomes, including new-onset atrial fibrillation, ventricular arrhythmia, hospitalisation due to heart failure or embolic events, or cardiovascular death.

**Results**
HCM patients exhibited lower RV ejection fraction (RVEF) and global peak systolic strains (radial/circumferential/longitudinal) on feature-tracking analysis of cine images than healthy controls. On follow up CMR imaging, RVEF, peak RV circumferential and longitudinal strains decreased over time while LVEF remained preserved. All patients were followed up clinically for a median duration of 4.4 years. Both reduced RVEF and RV longitudinal strain were independent predictors of ventricular arrhythmias and composite cardiovascular endpoint (arrhythmia, cardiac hospitalisation and cardiovascular death), after adjusting for baseline NYHA class, medication use, maximal LV wall thickness, and late gadolinium enhancement. Patients with RVEF <55% had a 3-fold increase in ventricular arrhythmias (HR 3.03, 95% CI 1.63 to 5.66, figure 1A) and a 2-fold increase in composite cardiac events (HR 2.05, 95% CI 1.23 to 3.41, figure 1B). Similarly patients in the lowest quartile of RV longitudinal strain (<16.3%) demonstrated a higher risk of ventricular arrhythmias (HR 2.20, 95% CI 1.61 to 3.84, figure 1C) compared to others.

**Conclusions**
Despite preserved LVEF, RVEF and strain decline over time in HCM. RVEF and strain predict the occurrence of adverse cardiovascular outcomes and may have a role in prognostic risk stratification in HCM.

**Introduction**
Cardiac amyloidosis is a disease of infiltration, typically by light chains (AL) or transthyretin (ATTR). We studied cardiac amyloidosis using diffusion tensor cardiovascular magnetic resonance (DT-CMR), which is the only non-invasive tool able to assess cardiac microstructure in-vivo.

**Methods and results**
Biphasic STEAM DT-CMR was successfully performed in 20 cardiac amyloidosis patients (10 AL, 10 ATTR) and 10 age and sex matched controls. Compared with controls, amyloid patients had higher mean diffusivity (MD); median [IQR] 1.46 [1.36–1.54] × 10⁻³ mm²/s vs 1.15 [1.03–1.20] × 10⁻³ mm²/s (p<0.001), shown in figure 1A. MD correlated with T1 (R²=0.76, p<0.001) and extracellular volume (ECV) (R²=0.47, p=0.004).

**Conclusion**
In cardiac amyloidosis, DT-CMR characterises the microstructural effects of infiltration, and increases in MD show good correlation with increases in ECV. The novel insights from DT-CMR offer a deeper understanding of pathological mechanisms in cardiac amyloidosis. With further development, DT-CMR might offer a gadolinium free assessment of amyloid burden, which is of particular value in renal failure.
A PROSPECTIVE LONGITUDINAL FOLLOW UP STUDY USING T1 AND T2 MAPPING SEQUENCES AND TWELVE-SEGMENT MYOCARDIAL ASSESSMENT TO IDENTIFY AND MONITOR MYOCARDIAL INFLAMMATION IN MYOSITIS

Background Myositis is a systemic autoimmune condition causing skeletal muscle inflammation and fibrosis as well as extra skeletal involvement. Cardiac involvement is well described and has morbidity and mortality. It can be diffuse or focal which can make assessment using conventional imaging techniques more difficult. To date the incidence is poorly defined using conventional cardiac investigations.

Purpose To investigate the reproducibility of a 12 segment ventricular myocardial model of T1 and T2 mapping in healthy volunteers and then to use this methodology in patients with myositis, comparing it to the current non invasive gold standard of troponin I level for cardiac involvement and then monitor how it changes with time and treatment.

Methods 19 Healthy volunteers were scanned at 1.5T. T1 (using a MOLLI sequence) and T2 mapping were performed
