The diagnostic yield of ILR insertion was 34%. ANS referrals trended towards greater diagnostic yield compared with clinicians and significantly more pacemaker indications. Our data suggest ANS patient selection for ILRs are at least comparable to clinicians.

50 ISCHAEMIA AND NO OBSTRUCTIVE CORONARY ARTERY DISEASE (INOCA): PREVALENCE AND PREDICTORS OF CORONARY VASOMOTION DISORDERS

Tom Ford*, Richard Good, Paul Rocchiccioli, Margaret McInteagert, Stuart Watkins, Harry Eteba, AaDil Shaukat, Mitchell Lindsay, Keith Robertson, Stuart Hood, Ross McGeoch, Robert McDaide, Eric Yi, Novalia Sidik, Peter McCartney, David Corcoran, Damien Collison, Christopher Rush, Naveed Sattar, Keith Oldroyd, Rhian Touyz, Colin Berry. 1University of Glasgow; 2NHS NWTC; 3West of Scotland Heart and Lung Centre, Golden Jubilee National Hospital, UK; 4University Hospital Hairmyres, East Kilbride, UK; 5British Heart Foundation Glasgow Cardiovascular Research Centre; 6NHS Greater Glasgow & Clyde

Background Ischemia and no obstructive epicardial coronary artery disease (INOCA) is a common clinical syndrome with distinct underlying causes.

Objective To evaluate the prevalence and predictors of microvascular and/or vasospastic angina (MVA/VSA) in an unselected cohort of angina patients referred for invasive coronary angiography with suspected ischaemic heart disease in whom obstructive coronary artery disease (CAD) is excluded.

Methods Prospective cohort study at two regional centres between November 2016 and December 2017 including patients with symptoms and/or signs of ischaemia prior to undergoing invasive coronary angiography (NCT03193294). Baseline risk was assessed (ASSIGN score) and validated questionnaires were completed prior to the angiogram including Rose angina, quality of life (EuroQOL [EQ-5D-5L]) and angina severity according to the Seattle Angina Questionnaire (SAQ). Patients with definite or probable angina without CAD [diameter stenosis <50% and/or FFR > 0.80] proceeded directly to assessment for disorders of coronary vasomotion. This involved an ad hoc interventional diagnostic procedure (IDP) using reference invasive tests for microvascular angina (MVA), vasospastic angina (VSA), both conditions or none. MVA and VSA groups were compared before logistic regression was performed to assess predictors of MVA and VSA.

Results Three hundred and ninety-one patients with angina were recruited before undergoing invasive coronary angiography during the study period. Overall, 185 (47%) of subjects had INOCA and 151 of these underwent an IDP. INOCA patients reported similar angina burden with worse quality of life than CAD subjects (EQ5D-5L index 0.60 v 0.65 units; P=0.041). The mean age of patients who underwent the IDP was 60.9 years, 74% were female and their median predicted 10-year IHD risk was 18.6% (10.6, 31.4). 78 subjects (52%)
had isolated microvascular angina, 25 (17%) had isolated vasospastic angina, 31 (20%) had both (MVA & VSA) only 17 (11%) had non-cardiac chest pain. Myocardial bridging of coronary artery was found in 22 (15%). Multivariate predictors of MVA included typical angina, inducible ischaemia but traditional cardiovascular risk factors were not associated. Smoking and age were independent predictors of VSA.

Conflict of Interest Nil

Introduction Patient understanding of angiography and angioplasty is often incomplete at the time of consent. Language barriers and time constraints are significant obstacles. New approaches are needed to support communication and decision making. To this end, we developed a multi-language animation describing the benefits, risks and alternatives of the procedures (please click to view www.explainmyprocedure.com). We introduced the animation into practice in a pilot quality improvement project and assessed patients’ understanding of the procedure before and after its introduction.

Methods Forty consecutive patients were interviewed, twenty who had watched the animation prior to their procedure and twenty who had not, to determine whether they felt completely informed, understood the benefits, the risks and the alternative treatments. Responses to these four questions were analysed categorically and ratios calculated for the animation group compared with the non-animation group (with 95% confidence intervals). STATA V10 was used for all analyses.

Results Table 1 shows that patients in the animation group (mean age 64 years) and in the no animation group (mean age 68 years) were well matched. Figure 1 shows that understanding of the procedure was greater in the animation group across all four questions. In the animation group there was a statistically significant 3-fold greater understanding of the risks of the procedure (ratio 3.0 (95% CI 1.2 to 7.7), p=0.023) and a 2.5-fold increase in the proportion of patients who felt completely informed before giving consent (2.3 (1.2 to 5.1), p=0.01). There were directional, but non-significant, increases in understanding of the benefits and alternatives of the procedure; ratios 1.6 (0.8 to 3.2), p=0.34 and 2.0 (0.6 to 6.9), p=0.45, respectively.

Conclusion Viewing animations of angiography and angioplasty before consent was associated with a greater understanding of the procedures and the associated risks. Multi-language narration has the potential to further improve communication surrounding consent. The approach is not limited to cardiology and has the potential to be applied to all specialties in medicine.

Current pharmacological approaches aimed at improving stent designs are limited by their inability to reduce endothelial damage following stent placement and improve healing. Here, we consider in vitro approaches that could be used to assess the effects of novel anti-oxidant stent coatings on damaged endothelial cells following stent placement. Oxidative stress is a physiological response to inflammation and can result in activation of intracellular signalling molecule, leading to pathological effects. One such molecule is calcium/calmodulin dependent protein kinase II (CaMKII). Hyper-activation of CaMKII is known to be directly linked to disease progression in the heart and it has been implicated in endothelial dysfunction. It is therefore of interest to examine how novel drug-free stent coatings might reduce or reverse oxidative damage following stent placement and whether CaMKII may be a potential target. Our initial experiments have used human umbilical vein endothelial cells (HUVECs), challenged with inflammatory and oxidative stress as a model for future investigations with novel stent coatings.

Novel stent-coatings were generated on 200 μm stainless steel wires (316L medical grade), and their antioxidant activity assessed at 8h and 24h using a DPPH (2,2-diphenyl-1-picrylhydrazyl) colorimetric assay and expressed as a percentage of scavenged to total radicals. Antioxidant activity was observed...
