associated with mortality (HR 0.646, 95% CI 0.135-3.097, p=0.585). On stepwise forward regression analysis, only undergoing any intervention (TAVI or AVR) remained a significant predictor of increased survival (HR 0.308, 95% CI 0.159-0.597, p<0.001) (table 1). ST2 (HR 1.020, 95% CI 1.003-1.037, p=0.022) and LnNT-proBNP (HR 1.258, 95% CI 1.036-1.594, p=0.022) were the only significant predictors for poor mortality (table 1).

Discussion Higher volume of EAT indexed to myocardial mass was not associated with mortality in patients with AS. The variables that did remain significant after adjustment were ST2, NT-proBNP and undergoing intervention.

Conclusions Higher EAT volume indexed to myocardial mass was not significantly associated with mortality after adjusting for other variables in patients with AS.

27 INHERITED CARDIOMYOPATHY CONDITIONS CLINIC IN DISTRICT GENERAL HOSPITAL IMPROVES ESC GUIDELINES IMPLEMENTATION AND MANAGEMENT OF PATIENTS WITH HYPERTROPHIC CARDIOMYOPATHY

Elton Luo, Kenneth Chan, Joycee Basu, Lindsey Tilling, Katrin Balkhausen, Sacha Bull. Royal Berkshire Hospital, Reading, UK

Background Hypertrophic cardiomyopathy (HCM) is the most common inherited cardiomyopathy and is frequently encountered in clinic. In many district general hospitals (DGH), the condition is frequently managed in general cardiology clinics with a small proportion referred to dedicated Inherited Cardiomyopathy Conditions (ICC) clinic in tertiary centres for complex treatments. We hypothesised that management of HCM patients would be improved by introduction of a dedicated ICC clinic at our district general hospital.

Purpose The purpose of the study was to evaluate the impact on patient management in a dedicated ICC clinic at our district general hospital. The outcome was determined by assessing adherence to the European Society of Cardiology (ESC) HCM guidelines before and after introduction of this clinic, hospital admission and mortality.

Methods We retrospectively reviewed the clinic records of patients with a diagnosis of HCM seen in the general cardiology clinic. A dedicated ICC clinic was established and the patient records of those with HCM assessed in the ICC clinic. In many district general hospitals (DGH), the condition is frequently managed in general cardiology clinics with a small proportion referred to dedicated Inherited Cardiomyopathy Conditions (ICC) clinic in tertiary centres for complex treatments. We hypothesised that management of HCM patients would be improved by introduction of a dedicated ICC clinic at our district general hospital.

Purpose The purpose of the study was to evaluate the impact on patient management in a dedicated ICC clinic at our district general hospital. The outcome was determined by assessing adherence to the European Society of Cardiology (ESC) HCM guidelines before and after introduction of this clinic, hospital admission and mortality.

Methods We retrospectively reviewed the clinic records of patients with a diagnosis of HCM seen in the general cardiology clinic. A dedicated ICC clinic was established and the patient records of those with HCM assessed in the ICC clinic over a 6-month period were also reviewed. Patient assessment and management were evaluated against ESC recommendations, including clinical risk stratification (symptoms, ventricular blood pressure monitoring, ambulatory blood pressure monitoring, 48-hour Holter monitoring, sudden cardiac death), imaging assessment, echocardiography and cardiac magnetic resonance (CMR); and patient counselling (exercise, genetic, and family counselling). Patient outcomes at 2-years were evaluated, including hospital admissions from cardiac causes (arrhythmia, stroke, chest pain, heart failure); new onset heart failure; and all-cause mortality.

Results Demographics were similar for HCM patients assessed in the ICC clinic (n=62, mean age 61±13), and general cardiology clinic prior to the introduction of ICC clinic (n=24, mean age 61±17). There were significant improvements in risk stratification by clinical assessment of symptoms, Holter monitoring, as well as formal SCD risk evaluation (table 1).

There was better compliance with ESC recommendations in imaging assessments; more patients underwent CMR and left ventricular outflow tract (LVOT) assessment in echocardiography in the ICC clinic cohort (table 2). None of the patients in either cohort met the clinical endpoint of SCD. Hospital admission from cardiac causes at 2-years was significantly lower in the patients assessed in ICC clinics (table 2).

Conclusions In this HCM cohort, introduction of a local ICC clinic led to improved patient care through better adherence to ESC HCM guidelines in particular with respect to clinical assessment, imaging and risk stratification as well as reduced hospitalisations from cardiac causes.
