significant difference in MACE during hospital admission between the two groups except for in-hospital mortality which was 5.26% higher in inter hospital transfer group. Kaplan Meier Survival analysis showed that the likelihood of survival at five years was 83% for direct admission vs 77.3% for inter hospital transfer with P value < 0.01. Additionally, one month mortality was significantly higher among inter hospital transfer group.

Conclusion In all the cohort of patients, in-hospital mortality, and five years mortality was significantly higher in inter hospital transfer group compared to direct admission group.

**46 GLUCOSE TRANSPORTER GLUT4/NITRIC OXIDE SYNTHETASE PATHWAY MEDIATES THE CARDIOPROTECTIVE EFFECTS OF THE INTRAVENOUS IMMUNOGLOBULINS TO THE DIABETIC HEART**

1Fawzi Babiker, 2Aisha Al-Kouh, 2Maie Al-Bader. 1Kuwait University, Kuwait University, Kuwait, 13100, Kuwait; 2Kuwait University

Background Ischemic heart disease (IHD) in combination with Diabetes Mellitus (DM) is a challenge of recent research and the role of intravenous immunoglobulin (IVIG) in the protection of the heart against ischemia/reperfusion (I/R) injury is not completely understood. The aim of this study is to investigate the role of IVIG in the protection of the diabetic heart against I/R injury.

Methods Hearts isolated from adult nondiabetic and diabetic Wistar rats (n=8) were used in this study. Hearts were treated with IVIG either two hours before sacrifice, before ischemia or at reperfusion. Hemodynamics data were acquired online using software designed specifically for that purpose. Infarct size was evaluated using 2,3,5-Triphenyltetrazolium chloride (TTC) staining. Expression levels of apoptosis markers (caspase 3 and 8), antioxidative enzymes, superoxide dismutase (SOD) and catalase (CAT) and Glucose transporters, GLUT1 and GLUT4 were evaluated by Western blotting. Pro-inflammatory cytokines levels. Interestingly, these treatments significantly (P<0.05) decreased apoptosis markers, pro-inflammatory cytokines and increased the anti-inflammatory cytokines levels. Interestingly, these treatments significantly (P≤0.05) increased eNOS phosphorylation and the expression of GLUT4 but not GLUT1.

Conclusion Treatment of the diabetic heart with IVIG selectively protected the heart at reperfusion in four- and six-weeks diabetic hearts and only when infused before ischemia in four weeks diabetic hearts. This protection followed a pathway using eNOS/Grut4 axis. Acknowledgement: We acknowledge the Health Science Animal facility for providing the animals. Rheumatic heart disease (RHD) remains a major source of morbidity and mortality in developing countries. A deeper insight into the pathogenetic mechanisms underlying RHD could provide opportunities for drug repurposing, guide recommendations for secondary penicillin prophylaxis, and/or inform development of near-patient diagnostics. We performed quantitative proteomics using Sequential Windowed Acquisition of All Theoretical Fragment Ion Mass Spectrometry (SWATH-MS) to screen protein expression in 215 African patients with severe RHD, and 230 controls. We applied a machine learning (ML) approach to feature selection among the 366 proteins quantifiable in at least 40% of samples, using the Boruta wrapper algorithm. The case-control differences and contribution area under the Receiver Operating Curve for each of the 56 proteins identified by the Boruta algorithm were calculated by Logistic Regression adjusted for age, sex and BMI. Biological pathways and functions enriched for proteins were identified using ClueGo pathway analyses. Adiponectin, complement component C7 and fibulin-1, a component of heart valve matrix, were significantly higher in cases when compared with controls (Table 1). Ficolin-3, a protein with calcium-independent lectin activity that activates the complement pathway, was lower in cases than controls (Table 1). The top
