transmembrane helices leading to an extracellular N-terminus and an extracellular loop between helices two and three. The C242T polymorphism causes a change of His72 to Tyr72. This change results in significant morphological changes of the extracellular loop of the p22phox, which is in the putative interactive region of the p22phox with the catalytic subunit (Nox2). This may interfere with their association, and subsequently result in a reduced cytochrome b function and a reduced ROS production by NADPH oxidase. These results give us insight into the molecular mechanism of this polymorphism in reducing vascular oxidative stress and may explain how this polymorphism is linked with reduced incidence of CHD.

**HEPATOCYTE GROWTH FACTOR-C-MET SIGNALLING ACTIVATES NOTCH TRANSLOCATION AND IS ASSOCIATED WITH SMOOTH MUSCLE CELL MINERALISATION IN VITRO**

doi:10.1136/hrt.2010.205781.60

Vascular calcification is an established pathological process that contributes to several forms of cardiovascular morbidity—notably, atherosclerosis. The molecular mechanisms involved continue to be explored. Hepatocyte growth factor (HGF) signalling, via its receptor c-MET, has been identified in association with atherosclerotic plaque development. We have demonstrated that overexpression of HGF in human smooth muscle cells (hSMC) accelerates their mineralisation. Reports demonstrating upregulation of the notch ligand 8, and the presence of a feedback loop linked to the c-MET pathway, raise the possibility that the effects of HGF on mineralisation may be mediated via notch signalling. We aim to test the hypothesis that notch signalling is involved in Ad-HGF-induced in vitro mineralisation of hSMCs. We demonstrate accelerated mineralisation in response to adenoaviral-mediated HGF overexpression, confirmed by alizarin red staining, calcium incorporation and increased alkaline phosphatase activity. In addition, we show upregulation and phosphorylation of c-MET and reduction of the mineralisation inhibitor osteopontin. We identify upregulation of the notch-3 intracellular domain via western blot analysis and, using immunocytochemistry, show an altered distribution of notch-3 in Ad-HGF-infected cells. Finally, we show (i) an attenuation of mineralisation in hSMCs following overexpression of NK4, the c-MET antagonist and (ii) that treatment of hSMCs with DAPT, the notch inhibitor, also decreased the rate of mineralisation compared with Ad-HGF infected cells and controls. These findings suggest a link with the notch pathway as a possible downstream effector of HGF and further elucidate a novel mechanism underpinning vascular calcification.

**CONTROL OF VASCULAR CELL INFLAMMATORY RESPONSES THROUGH TILRR, AN INTERLEUKIN 1 CO-RECEPTOR**

doi:10.1136/hrt.2010.205781.62

Monica Neilan, Xiao Zhang, Sheila Francis, Eva E Qwarnstrom. Cell Biology, Vascular Science, University of Sheffield, UK

Inflammatory responses are induced by members of the Toll-Like and interleukin (IL)-1 receptor family and controlled by NF-kB. We have identified an IL-1RI co-receptor, TILRR, which potentiates activation of NF-kB and inflammatory responses. We show that induction of amplification depends on formation of a TILRR-containing receptor complex, which imparts enhanced recruitment of the MyD88 adaptor to the signalling receptor IL-1RI, and induction of Ras-dependent amplification of NF-kB.1

We have confirmed expression of TILRR in vascular cells and have demonstrated a correlation of the level of TILRR expression with the level of NF-kB activity and inflammatory responses, induced by IL-1 stimulation and by mecanotransduction.

Our recent studies have demonstrated expression of TILRR in vascular endothelial cells using immunohistochemistry. Sections of perfusion-fixed, paraffin-embedded vascular tissue were stained using a specific rabbit polyclonal anti-TILRR antibody, followed by incubation with a biotinylated goat anti-rabbit antibody. Ongoing studies using wild type and ApoE−/− mice are designed to assess the impact of diet on TILRR expression and on its association with the signalling partner IL-1RI.

The major outer membrane protein (MOMP) of Chlamydia pneumoniae is a 40 kDa porin and represents approximately 60% of the outer membrane protein pool. Previous studies have shown that MOMP can dampen down T-cell-mediated immune responses. We decided to assess if this effect could have an impact on atherosclerotic plaque development. We used recombinant Mycobacterium vaccae (M vaccae) vectors expressing MOMP (with and without signal sequence) to vaccinate ApoE−/− mice intranasally. Animals received one initial dose and two booster doses 3 weeks apart and continued with a standard Chow diet for another 4 weeks. Control mice received phosphate-buffered saline or were left untreated. Plasma collected before immunisation and at termination was used to measure levels of interferon γ, interleukin (IL)-4 and IL-10 and also IgG1 and IgG2b. Atherosclerotic plaque development was assessed using paraffin sections of the brachiocephalic artery. Our results show that intranasal administration of M vaccae vectors expressing MOMP, with or without signal sequence, promotes antiatherogenic T-cell responses and halts the development and progression of atherosclerotic plaques in ApoE−/− mice.

**INVESTIGATING THE IMPORTANCE OF HEPARAN SULPHATE IN DETERMINING ENDOTHELIAL PROGENITOR CELL FUNCTION**

doi:10.1136/hrt.2010.205781.63

K Williamson, 5S Haque, 5I N Bruce, 5S E Stringer, 5M Y Alexander. Cardiovascular Research Group, University of Manchester, Manchester, UK; 5ARC Epidemiology Unit, University of Manchester, Manchester, UK; 5University of Manchester, Manchester, UK

The increased risk of cardiovascular disease with age may, in part, be due to a decline in the function of endothelial progenitor cells (EPCs). Cell surface heparan sulphate proteoglycans (HSPGs) can
The relationship between self-reported sleep duration and von Willebrand factor (vWF), The relationship between self-reported sleep duration characterised occupational cohort.

Rationale Sleep is an emerging risk factor for cardiovascular disease (CVD). We examined the relationship between sleep duration and haemostatic factors important in CVD development, in a well-characterised occupational cohort.

Methodology The relationship between self-reported sleep duration and von Willebrand factor (vWF), fibrinogen and factor VII in 6400 individuals from the Whitehall II study was examined.

Results Owing to significant gender interactions (p<0.001), the analysis was stratified by gender. After multiple adjustments, vWF levels were significantly higher in men with both short (<6 h per night; 1.05 (95% CI 1.01 to 1.09) and long (>8 h per night; 1.05 (95% CI 1.02 to 1.08)) duration of sleep compared with those who slept 7 h (p<0.05 for both). In women, levels of vWF were significantly higher in individuals who slept >8 h (1.11 (95% CI 1.06 to 1.16)) than in those who slept for 7 h (p<0.05). This difference was observed in premenopausal and postmenopausal women (p<0.05 for each). The association seen in women appears to be non-linear (p=0.02), but not in men (p=0.09). No statistically significant associations between sleep duration and fibrinogen or factor VII were seen.

Conclusions Men sleeping for both short and long periods had higher vWF levels than those who slept for 7 h. In women, there was a significant non-linear association with the highest levels mainly seen in long sleepers, irrespective of menopausal status. No major associations between sleep and either factor VII or fibrinogen were observed. Further longitudinal studies are required to fully investigate possible temporal relationships between sleep and vWF and the possible associated risk of CVD.
