**e0389** CLINICAL PROFILE OF PREMENOPAUSAL WOMEN WITH CORONARY HEART DISEASE

doi:10.1136/hrt.2010.208967.389

Rongjing DING, Dayi Hu. Heart and Vascular Center, Beijing University People’s hospital, Beijing China

**Objective** To study the clinical profile of premenopausal women with coronary heart disease.

**Methods** 114 premenopausal women with chest pain were classified into coronary heart disease group and control group by coronary angiography. Risk factors, clinical symptoms and the coronary angiographic characteristics were investigated retrospectively.

**Results** The risk factors of premenopausal women with coronary heart disease were hypertension, diabetes and hyperlipidaemia. Typical angina pectoris was an important character. The typical change of ECG in premenopausal women with coronary heart disease was elevation or depression of ST, but not T wave. The sensitivity and specificity of Exercise stress testing or SPECT for premenopausal women with coronary heart disease were 67.7% and 32.2%, 40.9% and 59%, respectively. Single vessel coronary lesion was found more frequently in Premenopausal Women with coronary heart disease, and the left anterior disending artery was the most frequently involved vessel.

**Conclusion** Hypertension, Diabetes and/or hyperlipidaemia are major risk factors in premenopausal women with coronary heart disease. Women with typical angina pectoris and ST changes should be cautioned coronary heart disease. Nonvasive testing is a poor diagnosis method for young women with coronary heart disease, but can be used as exclusive marker.

**e0390** RELATIONSHIP BETWEEN RETINAL VASCULOPATHY AND CORONARY ARTERY DISEASE

doi:10.1136/hrt.2010.208967.390

**Objective** To study relation between the stressing blood sugar and hs-CRP and the no or slow reflow occurred in patients with acute myocardial infarction after primary PCI.

**Methods** 253 patients be suspected STEMI with chest pain were admitted to this study, all patients were selected from heart center of our hospital and the time of D-to-B was less than 6 h. were divided into group of no or slow reflow and group of normal control according to the results of CAG.

**Results** 26 patients had no or slow reflow, and the stressing blood sugar, hs-CRP of group with no reflow were super to the control group obviously (p<0.05 or p<0.01).

**Conclusion** detection of stressing blood sugar and hs-CRP were correlated to the occlusion of no or slow reflow after primary PCI, and can be used to predict the Prognosis.

**e0391** VALUE OF TESTING OF CAROTID ARTERY PLAQUE JOINT HS-CRP TO THE DEGREE OF CORONARY STENOSIS IN PATIENTS WITH CORONARY HEART DISEASE

doi:10.1136/hrt.2010.208967.391

Sheng Yang, Fu Qiang, Wei Peng, Li Zhenyong Yi. Department of Cardiology, Xuzhou Central Hospital

**Objective** To study the predictive value of score of intima-media thickness (IMT), Crouse in carotid artery plaque, and serum levels of high sensitivity C-reactive protein (hs-CRP) in the degree of coronary stenosis of patients with coronary artery disease.

**Methods** A total of 110 patients suspected coronary heart disease with chest pain were admitted to this study. They were divided into two groups: group of coronary heart disease and group of normal control according to the results of CAG. All patients underwent carotid ultrasonography within a week, and carried out the testing of serum concentrations of hs-CRP in second hospitalised day, to assess the determining and forecasting value of score of IMT and Crouse in carotid artery plaque, combining with serum levels of hs-CRP in the degree of coronary stenosis of patients with coronary artery disease.

**Results** Serum concentrations of hs-CRP, score of IMT, Crouse of group CHD were significantly higher than those of group non-CHD (p<0.01), and each mentioned indicators in group CHD was positively correlated with the degree of coronary stenosis(r>0.6, p<0.05). Taking Crouse points≥10.7 as a standard, its sensitivity was 78.5%, positive predictive value was 89.9%, specificity was 79.0%, negative predictive value was 58.0%.

**Conclusion** There was a high consistency between serum concentrations of hs-CRP, score of IMT, Crouse and the degree of coronary stenosis, so we can use serum concentrations of hs-CRP, score of IMT, Crouse as a prediction method to coronary heart disease in patients with carotid artery atherosclerosis.
