Objective TO evaluate the correlation between acute lipids level and on-statin treatment lipids and 1 year major adverse cardiovascular and cerebrovascular events (MACCE), including cardiac death, ischaemic stroke, and recurrent myocardial infarction in patients with ST-elevation myocardial infarction (STEMI) undergoing primary percutaneous coronary intervention (PCI).

Methods Based on the LDL-C level within 24 h after admission, consecutive 624 patients with STEMI undergoing primary PCI were classified into the normal range of LDL-C<3.37 mmol·L⁻¹ (n=380), the critical range of LDL-C 3.37~4.14 mmol·L⁻¹ (n=159) or the elevated range of LDL-C>4.14 mmol·L⁻¹ (n=85). Of these 624 patients, serum lipids levels of 555 patients after statins treatment for 4 weeks underwent follow-up in outpatient settings. Based on the results of follow-up, these 555 patients were divided into the targeted group (LDL-C<1.81 mmol·L⁻¹, n=77) or the non-targeted group (LDL-C=1.81 mmol·L⁻¹, n=258). The end point was 1 year MACCE.

Results When compared between different lipid ranges (the normal, the critical and the elevated) of patients, the acute lipid level was significantly lower than group B, there were no significant difference between group B and group C. Group A, group C differences were statistically significant illustrated the LVEF of group A was significantly lower than group B and group C.

Conclusion Glibenclamide would increase myocardial ischaemic area in patients with acute myocardial infarction and type 2 diabetes mellitus. Glibenclamide increases the possibility of malignant arrhythmias in the patients with acute myocardial infarction and type 2 diabetes mellitus.

Background To evaluate the contrast research in safety and effective time between nadroparin and dalteparin before elective percutaneous coronary intervention (PCI) in Chinese population. Investigating the relationship among anti-Xa activities APTT and ACT, and if it help to use nadroparin and dalteparin.

Methods A total of 101 consecutive patients undergoing elective PCI were randomised to either nadroparin (50 cases) or dalteparin (51 cases) group for procedural anticoagulation. According to description, the patients in nadroparin or dalteparin group were given nadroparin (0.01 ml/kg) or dalteparin (120 IU/kg) subcutaneously more than 48 h twice per day before PCI. Serial plasma anti-Xa activities ACT and APTT were measured before and after nadroparin and dalteparin were injected. Then coronary angiography (CAG) and PCI was performed. Bleeding complications were classified according to Thrombolysis in Myocardial Infarction (TIMI) criteria. All patients were monitored for anticoagulation before and after PCI and adverse events (ie, death, myocardial infarction, demands for revascularization) 30 days after PCI.

Results 101 patients were completed. 1. The proportion, plasma anti-Xa activities of patients in nadroparin or dalteparin group above 0.5 IU/ml, exceeded 92% after 4 h subcutaneous injection. The proportion descended to 74% and 36% in nadroparin group after 8 h and 12 h, 54.9% and 23.5% in dalteparin group, which descend more, but had no significantly difference compared with nadroparin group. After 24 h and 48 h, the proportion of plasma anti-Xa activities of patients in both groups are above 0.5 IU/ml, achieved steady state and exceeded 96.0%. 2. The plasma anti-Xa activities correlated with APTT significantly in both groups after 4 h, 24 h and 48 h (p<0.01). The plasma anti-Xa activities hardly correlated with ACT, and have no difference in Statistics (nadroparin group p=0.075, dalteparin group p=0.095). 3. There were no adverse events in 30 days, and no significantly difference about bleeding events (6.0% vs 3.9%, p=0.05) between the two groups.

Conclusion The subcutaneous injection of nadroparin or dalteparin for anticoagulation in patients before elective PCI is safe and effective. Anticoagulation effects can be maintained for at least 8 h. ACT can response to the anticoagulation effects of nadroparin or dalteparin by subcutaneous injection. ACT cannot response to the effective anticoagulation effects of nadroparin or dalteparin by subcutaneous injection.
into the present study from January 2006 to July 2009. Demographic information, concomitant diseases, peri-operative laboratory examinations, angiographic features, and surgery information of consecutive patients who underwent PCI were collected.

**Results** A total of 13,922 patients were recorded in the database, of which 9.03% (1,257/13,922) had previous PCI. Univariate analysis revealed that patients with prior PCI had significant higher prevalence of hypertension, diabetes mellitus and hyperlipidaemia than those without prior PCI. In addition, the percentage of patients with prior CABG was higher in the former group (6.0% vs 1.9%, p<0.001). In multivariable logistic regression analyses adjusted for demographic, clinical, angiographic and procedural factors, elderly age (OR 1.01, 95% CI 1.00 to 1.01), male (OR 1.74, 95% CI 1.48 to 2.04), hypertension (OR 1.36, 95% CI 1.19 to 1.54), diabetes mellitus (OR 1.45, 95% CI 1.24 to 1.65), hyperlipidaemia (OR 1.30, 95% CI 1.06 to 1.57) and prior CABG (OR 3.57, 95% CI 2.52 to 4.51) were identified as independent risk factors of secondary PCI. Additionally, history of prior CABG was the most important predictor of secondary PCI.

**Conclusions** Risk factors associated with secondary PCI include elderly age, male, hypertension, diabetes mellitus, hyperlipidaemia and prior CABG, of which previous CABG was the most important.

**Objective** To determine whether EECP-integrated standard therapy would reduce the major adverse cardiovascular events in patients with coronary artery diseases and improve the quality of life.

**Method** A total of 194 patients aged from 32 to 75 years old with coronary artery diseases from Sept. 2008 to Dec. 2009 in 4 hospitals affiliated to Sun Yat-sen University were enrolled into the trial. Subjects were randomised to be allocated either to EECP plus standard therapy group or standard therapy group, and followed for 0.5 to 1.5-year. The coronary artery disease in all patients was documented by coronary angiography, or a history of prior myocardial infarction or prior coronary revascularization. Patients in standard therapy group were treated with guideline-driven therapeutic strategy, and patients in EECP group were given 36 h of EECP in addition to the guideline-driven therapeutic strategy. Repeated EECP were prescribed to patients with any recurred ischaemic symptoms, or new ischaemia, or no symptoms in 12 months later. Follow-up visits were performed at 1, 3, 6, 12 months and each year therefore from the inclusion.

**Results** The primary composite endpoints of myocardial infarction, revascularisation, readmission to hospital due to stroke and ACS occurred in 6 of 104 (5.77%) patients in EECP group compared with 9 of 91 (9.89%) in standard therapy group (p<0.05). There was 1 death in both groups respectively. The incidence of minor skin damage was about 8% in EECP group, causing EECP therapy in 3 patients to be prematurely terminated.

**Conclusion** An EECP-integrated standard therapy significantly reduced major cardiovascular events in patients with documented coronary artery disease.

**Objective** To confirm the effect of Shengmai injection in improving cardiac function in patients with acute coronary syndrome (ACS) and to explore its influence on inflammatory reaction in patients.

**Methods** Ninety ACS patients were randomised into two groups, the control group, treated with conventional therapy and the SMI group, treated with SMI. The patients’ cardiac function was noted and the high sensitive C-reactive protein (hs-CRP) in venous blood was measured before treatment and 1 week and 2 weeks after treatment, so as to observe and compare their changes in the two groups.

**Results** The cardiac output, stroke volume and ejection fraction in the SMI group after 3 weeks of treatment were all higher than those in the control group (p<0.05). The serum content of hsCRP was reduced in both groups, but the reduction in the SMI group was more significant than that in the control group.

**Conclusion** SMI could improve cardiac function and further inhibit the inflammatory reaction in patients with ACS.

**Objective** To observe the immediate and recent treatment effects of applying the aspiration catheter in patients with ST-elevation myocardial infarction (STEMI) undergoing primary percutaneous coronary intervention (PCI).

**Methods** From March to June 2010, we enrolled the STEMI patients presenting with TIMI Flow Grade 0 or 1 in the infarct related artery (IRA) at baseline CAG undergoing primary PCI. The aspiration catheter (Medtronic Inc., Export?) was applied immediately to aspirate the intracoronary thrombus. Whether predilating and/or stenting were decided by the blood flow and the condition of lesions. The patients from October 2009 to February 2010 who was diagnosed as STEMI and received non-aspiration were enrolled as control group. The immediate and recent clinical outcomes of applying the aspiration catheter were compared between the two groups.

**Results** There were 25 cases in Group thrombus-aspiration (2 cases of subacute stent thrombosis). After having aspirated the intracoronary thrombus using the aspiration catheter, 14 cases of STEMI recovered immediately (9 cases received direct stenting; 5 cases implanted stents after balloon predilatation, and had satisfied results; 2 cases of subacute stent thrombosis received the antithrombotic therapy, included intravenous infusion of Ximweining for 36 h in CCI immediately after recovering TIMI grade-3 flow). 10 cases recovered TIMI 1-2, 1 cases also showed no-reflow. All of the 11 cases received the balloon predilatation and stenting, only one showed slow flow, the others recovered. There was no other severe complication during and after the operation. There was no in-stent thrombosis during 1 month follow-up, and the cardiac function improved largely. There
