ARVC or sudden death (OR=7.300, 95% CI 1.606 to 33.177, p=0.010), the accordion sign (OR=7.000, 95% CI 1.509 to 32.465, p=0.015) and number of regions with myocardial fibrosis (OR=2.204, 95% CI 1.116 to 4.354, p=0.023) were independent predictors for life-threatening ventricular arrhythmia in ARVC.

**Conclusions** MRI is the optimal imaging approach for detecting ARVC. Familial history of ARVC or sudden death, the accordion sign and number of regions with myocardial fibrosis were associated with an increased risk of life-threatening ventricular arrhythmia in patients with ARVC.

**e0605** "ONE-STOP SHOP" EXAMINATION OF COMPLICATED AND COMPLEX CONGENITAL HEART DISEASE WITH MRI

1Lu Minjie, 1Zhao Shihua, 1Jiang Shiliang, 1Lv Jianhua, 2Zhang Yan, 2Renate Jerrecic.
1Fuwai Hospital; 2Siemens Healthcare Group

**Objective** To evaluate the diagnostic value of MRI in complicated congenital heart disease, comparing with echocardiography and x-ray cardio-angiography.

**Methods** 20 patients with complicated or complex congenital heart disease (male 12, female 8, mean age 17.8 y, ranging from 3–46 y) underwent MR examination. A wireless vector ECG-gating was used for triggering; all the sequences were applied with breath hold or free breathing. Turbo spin echo and multiple gradient echo sequences (FLASH fast low angle shot and TrueFISP (true fast imaging with steady-state precession.) with TSENSE (adaptive sensitivity encoding incorporating temporal filtering) and TREAT (time resolved echo-shared technique) were used to evaluate the morphology, function, flow status of the heart. MR findings were compared with the results of echocardiography and x-ray cardio-angiography.

**Results** All the examination were accomplished successfully and diagnostic MR images were obtained satisfactory. The mean total scan time was 38 min ranging from 29–55 min. According to the main malformation diagnosed by MRI, double-outlet of right ventricle (DORV) were 11 cases, single ventricle were 3 cases, main malformation diagnosed by MRI, double-outlet of right ventricle (DORV) were 11 cases, single ventricle were 3 cases, stenosis or aneurysm of the right coronary artery (RCA) from left circumflex artery. Transthoracic echocardiography showed the right coronary artery (RCA) aneurysm and RCA fistula connecting to the right ventricular (RV). Aortography revealed the presence of a right coronary sinus of Valsalva aneurysm (SVA)-RV fistula and the originating of right coronary artery (RCA) from left circumflex artery (LCX). She was diagnosed as having a gigantic SVA to right ventricle fistula and a single origin of the coronary arteries. Successful transcatheter closure of the fistulous ostium was performed.

**e0607** ANALYSIS ON EARLY DIAGNOSIS GRADING MODEL OF ACUTE AORTIC DISSECTION

Liu Qiming, Tang Ming, Zhou Shenghua, Chai Xiangting. Department of emergency, Second Xiangya Hospital, Central South University, Changsha, Hunan

**Objective** To investigate the features of the clinical manifestation, laboratory data and imageology information in acute Aortic Dissection (AD) patients, to find the early, right and easy grading model of diagnosing AD.

**Method** Analyze the clinical manifestation, Laboratory data and imageology information of 182 AD patients, who were our patients at Emergency Department in last three years, and meanwhile, compared them with 184 chest and back ache patients, to search the early diagnosis grading model of AD.

**Results** If 5 score was the standard of the grading system to early diagnose AD on the basis of logistic regression equation and clinical practice, the sensitivity of AD forecast is 96.7%, specificity is 81.0%.

**Conclusions** We can improve the emergency diagnose level of AD through establishing the early grading model which contains the stabling and severe pain, distinct rise of the blood pressure, asymmetry of the blood pressure and/or the pulse, wide arteriae aorta and/or mediastinum on chest x-ray, obvious rise of D-dimmer.

**e0608** A NITINOL OCCLUDER AND A SPECIAL DELIVERY DEVICE FOR PATENT DUCTUS ARTERIOSUS (PDA) CLOSURE

Jiang Hai-bin, Zhao Xian-xian, Zong Gang-jun, Bai Yuan, Han Lin, Qin Yong-wen. Changhai Hospital

**Background** Nitrol occluders used for patent ductus arteriosus (PDA) may result in the stenosis of aortic and pulmonary artery when applied for smaller-sized children. The present study sought to design and develop an improved nitinol occluder and delivery system, and to verify the reliability and safety of this device on canine model of PDA.

**Methods** A canine FDA model was established by anastomosing the internal jugular vein with the left pulmonary artery and the descending aorta in an end-to-side fashion. The effects of the novel nitinol occluder and its delivery system were followed-up for 6 months after the closure.

**Results** FDA was successfully established in 10 out of 18 dogs and was treated by transcatheter occlusion with the novel nitinol occluder. Postoperative echocardiography showed that the location and shape of the occluder were normal without any regurgitation. Morphological examination revealed that the surface of the occluder was covered by a grey membrane-like tissue, which was identified as endothelial tissue by histological and electron microscopy examinations. There was no corrosion or severe inflammation on the
