THE VALUE OF SERUM HOMOCYSTEINE LEVEL IN EVALUATION OF OXIDATIVE STRESS IN ATRIAL FIBRILLATION PATIENTS WITH HEART FAILURE

Shipeng Wei, Lihua Zhong, Qinghai Yang, Yuanyuan Xu, Yanjun Chen, Yue Li. The 4th Clinical Hospital of Harbin Medical University

Background Serum homocysteine, an intermediate, is produced during the metabolism of methionine. It has been related to the development of cardiovascular diseases, such as coronary heart disease, heart failure and so on. On the other hand, it is a long-time issue whether atrial fibrillation will affect the mortality among patients with heart failure, which is still controversial. We argue that atrial fibrillation at least will alter the status of oxidative stress in patients with heart failure.

Methods 124 (72 men, mean age 64.1±10.5) patients from our hospital between January and June, 2010 were recruited. They were divided into four groups as follows: group 1, control, n=40; group 2, patients of heart failure (NYHA III–IV), n=24; group 5, patients of atrial fibrillation (NYHA I–II or over), n=24 and group 4, patients of atrial fibrillation with heart failure (NYHA III–IV), n=56. Homocysteine and C reactive protein (CRP) level were measured after hospitalisation.

Result There were no significant difference between the first three groups both in homocysteine (15.0±2.5 vs. 13.2±3.7 vs. 14.6±7.2) and CRP (4.5±4.0 vs. 6.5±5.2 vs. 6.8±5.1) level. The p values were 0.36, 0.63, 0.44 for homocysteine and 0.57, 0.98, 0.64 for CRP respectively. While there was a huge difference between group 4 (homocysteine, 21.8±6.5; CRP, 25.2±13.1) and others groups, p value were all below 0.0001 for both of homocysteine and CRP.

Conclusion Our data indicated that the status of oxidative stress was much more obvious in heart failure patients (NYHA III–IV) with atrial fibrillation. In other words, atrial fibrillation and heart failure made patients highly stressed.

EVALUATION OF THE WHOLE AND REGIONAL MYOCARDIAL FUNCTION OF LEFT VENTRICLE IN DOGS WITH CONGESTIVE HEART FAILURE INDUCED BY FAST RIGHT VENTRICULAR PACING

Zhao Ting, Wang Ke. Department of Cardiology, The First Affiliated Hospital of Dalian Medical University

Objective Use the Doppler and strain rate imaging (SRI) to evaluate the systolic and diastolic function of the whole and regional ventricular myocardial in congestive heart failure dog models induced by rapid ventricular pacing, and in order to provide more mature and sound methods and parameters to assess the clinical tachyarrhythmia left heart function.

Methods 13 healthy mongrel dogs received rapid right ventricular pacing 4 weeks at the rate of 230 beats per minute, to establish congestive heart failure models. The diastolic diameters of the left ventricle (LVEDd), left ventricular end diastolic volume (LVEDV), left ventricular end systolic volume (LVESV), ejection fraction (EF), diastolic flow velocity E and A wave, E/A, and E wave deceleration time (EDT) were measured before operation and after pacing of 4 weeks. Meanwhile, the peak systolic velocities were measured by Doppler quantitative tissue velocity image at four mitral ring sites (LV septum, LV lateral wall, LV inferior wall, LV anterior wall). At SRI condition, analysis was performed in basal and mid of septal and lateral walls in the apical 4-chamber view, in basal and mid of inferior and anterior walls in the apical 2-chamber view. All the walls SRI and SR curves were obtained, and the peak strain rate in every cardiac cycle, such as peak systolic strain (FSS), and peak systolic strain rate (SRS), peak diastolic strain (FDS) were recorded.

Result 1. After 4 weeks, compared with prior pacing, the following parameters increased significantly (p<0.01): the LVEDd, LVEDV, LVESV and Tei index. While LVEF of CHF dogs decreased significantly (p<0.01). 2. After 4 weeks, Compared with prior pacing, the peak systolic velocities at four mitral ring sites decreased significantly (p<0.01, or p<0.05). 3. After 4 weeks, Compared with prior pacing, the FSS and SRS in basal and mid of LV walls decreased significantly (p<0.01). While, the gradient of the FSS and SRS among the basal and mid of LV walls all disappeared (p>0.05). For example, the FSS in basal of LV walls decreased significantly (p<0.01): LV septum (5.7±2.5% vs 15.3±2.4%), LV lateral wall (7.3±1.2% vs 15.8±1.6%), LV inferior wall (4.9±3.8% vs 15.7±1.6%), LV anterior wall (6.6±0.6% vs 15.5±1.9%). The SRS in basal of LV walls decreased significantly (p<0.01): LV septum (1.4±0.4 S^-1 vs 1.4±0.4 S^-1), LV lateral wall (1.5±0.5 S^-1 vs 2.5±0.5 S^-1), LV inferior wall (1.0±0.3 S^-1 vs 1.8±0.4 S^-1), LV anterior wall (1.4±0.4 S^-1 vs 2.6±0.7 S^-1). 4. Compared with prior pacing, peak velocities of E and A waves, E/A and EDT showed no difference (p>0.05). However, the FDS in basal and mid of LV walls decreased significantly (p<0.01). While, the gradient of the FDS among the basal and mid of LV walls all disappeared (p>0.05). For example, the FDS in basal of LV walls decreased significantly (p<0.01): LV septum (7.1±1.2% vs 15.6±2.7%), LV lateral wall (7.5±1.1% vs 14.9±1.7%), LV inferior wall (6.6±1.5% vs 15.6±1.5%), LV anterior wall (6.5±1.0% vs 15.5±2.5%).

Conclusion After rapid ventricular pacing, congestive heart failure occurred in these experimental dogs, not only did the whole and regional myocardial systolic function decreased significantly, but also did to some extent the ventricle diastolic function changed. SR and SRI can be used to evaluate systolic and diastolic regional myocardial function in CHF dog models induced by rapid ventricular pacing and may provide more mature and sound parameters to assess the left heart function.

INITIAL EXPERIENCE OF SYNCHRONISED ELECTRICAL CARDIOVERSION FOR ATRIAL FIBRILLATION AFTER BIPOLAR RADIOFREQUENCY ABLATION MAZE OPERATION

Han Jingsong, Wang Hushan, Wang Zengwei, Li Xinmin. Department of Cardiovascular Surgery General Hospital of Shenyang Military Command

Background The purpose was to explore clinical experience of electrical cardioversion for atrial fibrillation (AF) after bipolar radiofrequency ablation Maze operation.

Methods From July 2006 to July 2009, 225 patients underwent bipolar radiofrequency maze operation for AF Out-patient were followed up after discharge on a regular basis. If effects of oral administration drugs such as digoxin, amiodarone and metoprolol were not obvious, with AF staying alive, patients should receive electrical cardioversion therapy. There were 15 cases underwent cardioversion therapy. After admission, ECG monitoring was needed. After intravenous anaesthesia using propofol, electrical cardioversion therapy was carried out with dose of 1-2 J/kg. Three times had they failed to turn to normal sinus rhythm (NSR), cardioversion be given up.

Results Four cases within 6 months after operation were given electrical cardioversion, three cases (75%) turned to NSR and one case (25%) was in AF instantly, the same until now. Of nine cases more than 6 months after operation, four cases (44.45%) turned to NSR instantly, two cases (22.22%) were still in AF, three cases...
(33.33%) were in junctional rhythm, however, five cases (55.56%) were in NSR, three cases (33.33%) were in AF and one (11.11%) was in junctional rhythm by far. Of three cases more than one year after operation, two cases (66.67%) were in NSR, one case (33.33%) was in AF. The cardiac function (NYHA) of 84.62% was gradeI and 15.38% gradeII. No thrombo-embolism occurred. Sinus bradycardia occurred in two cases during hospitalisation. 13 patients were followed up, reviewing ECG and echocardiography. The overall results of follow-up of cardiac rhythm were NSR in eight cases (61.54%), AF in four cases (30.77%), and junctional rhythm in one case (7.69%). Within seven cases whose heart rhythm immediately were able to turn to NSR, one case converted to AF later, the rate of maintenance of NSR was 85.71%, however, six patients could not be transferred into NSR instantly, only two cases (33.33%) turned into NSR. In NSR group left atrial diameter ECG (LAD) values reduced significantly after cardioversion ($t=6.9580, p=0.0000$), while LAD in AF group had no significant changes ($t=0.7308, p=0.4925$). The successful transfer rate was 71.43% in patients whose AF duration was less than 5 years and was 50% in patients whose AF duration was more than 5 years. There was no significant difference between the two AF duration groups ($X^2=0.174, p=0.6758$).

**Conclusion** Electrical cardioversion after bipolar radiofrequency maze operation was an effective option for the treatment of AF. The best time for cardioversion was within 6 months, which had high immediate success rate and be able to maintain a higher rate of NSR. Those who can be instantly converted to NSR, NSR maintenance rates are relatively high, but cannot be converted to NSR immediately who were less likely to NSR. With the prolonged time, successful rate of turning to NSR after electrical cardioversion reduced gradually. The effect of electrical cardioversion would be better if LAD were significantly reduced.

**e0664** CLINICAL RESEARCH ON INFLUENCE FACTORS OF PULMONARY ARTERY SYSTOLIC PRESSURE DERIVED FROM TRICUSPID REGURGITATION BY ECHOCARDIOGRAPH

doi:10.1136/hrt.2010.208967.664

Kang Lihui, Zhang Banwei, Huo Yong, Yang Ying, Qi Litong, Peking University First Hospital

**Objective** To explore which factors influence PASP calculated by echocardiograph through tricuspid regurgitation pressure gradient. **Methods** The retrospective study recruited 869 consecutive patients of Department of Cardiology in Peking University First Hospital, excluding patients who had acute myocardial infarction, pericardial effusion, congenital heart diseases, acute pulmonary embolism and organic tricuspid diseases. Their admission NYHA classification, N-terminal pro-B-type natriuretic peptide (NT-proBNP), echocardiographic and other clinic data were collected. Pulmonary artery systolic pressure (PASP) was derived from tricuspid regurgitation pressure gradient (TRPG) by echocardiograph. We analysed the correlations between PASP and age, sex, renal function, cardiopulmonary diseases and echocardiograph parameters, using single factor analysis and multivariate linear regression analysis.

**Results** Among these patients, 658 were found to have TR, with a proportion of 75.7%. PASP was independently correlated to chronic obstructive pulmonary disease (COPD) (B (SE): 2.489 (1.212), $p=0.027$), chronic pulmonary embolism (B (SE): 9.222 (2.175), $p<0.001$), aortic stenosis (B (SE): 18.846 (3.545), $p<0.001$), aortic regurgitation (B (SE): 2.586 (1.091), $p=0.029$), mitral regurgitation (B (SE): 2.093 (0.934), $p=0.025$) and hypertension (B (SE): 1.560 (0.677), $p=0.022$), but not to other cardiovascular diseases such as cardiomyopathy, atrial fibrillation, coronary heart diseases and renal function ($p>0.05$). PASP had independent correlation with both NYHA classification (B (SE): 3.701 (0.468), $p=0.002$) and NT-proBNP (B (SE): 2.235 (0.569), $p<0.001$). PASP was correlated to TR severity positively (B (SE): 5.801 (0.798), $p<0.001$), but not parallel to it. Age was an important predictor of PASP (B (SE): 0.081 (0.027), 95% CI (0.023 to 0.154), $p<0.001$), with an average increase in PASP of 0.81 mm Hg per decade.

**Conclusions** Tricuspid regurgitation is common in cardiac patients. PASP was independently correlated to COPD, chronic pulmonary embolism, left ventricular valve diseases and hypertension, but not to cardiomyopathy, atrial fibrillation, coronary heart diseases and renal function. PASP elevated with the increase of NYHA classification and NT-proBNP. It may play an important role in the evaluation of heart function. PASP should not be substituted by TR severity on the valuation of pulmonary circulation pressure. Age was an important predictor of PASP.
