premature ventricular beats of ex vivo heart, under the acute adrenergic challenge, they significantly enhanced the frequency of premature ventricular beats.

**Conclusions** BPA promotes arrhythmogenesis in female rat heart by induced DADs, and effects of BPA and E2 are synergistic instead of additive.

**RENALASE DEFICIENCY IN HEART FAILURE—A NOVEL MECHANISM UNDERLYING CIRCULATING NOREPINEPHRINE ACCUMULATION**

DOI: 10.1136/hrt.2010.208967.181

Gu Rong, Lu Wen, Xie Jun. Department of Cardiology, Affiliated Drum Tower Hospital, Nanjing University Medical School, Nanjing, China

**Background** Sympathetic overactivity and catecholamine accumulation are important characteristic findings in heart failure, which contribute to its pathophysiology. However, the mechanism underlying circulating catecholamine accumulation remains largely unclear.

**Objective** To identify a novel mechanism underlying norepinephrine accumulation in a rat model of heart failure.

**Methods and results** Initially, we constructed a rat model of unilateral renal artery stenosis and found that the expression of renalse, a previously identified secreted amine oxidase, was markedly reduced in the ischaemic compared to the non-ischaemic kidney. Subsequently, we utilised an isolated perfused rat kidney model to demonstrate that the clearance rate of norepinephrine decreased with reduction of either perfusion flow or pressure. On the basis of these findings, we hypothesised that the reduced renal blood supply which occurs in heart failure would result in impaired synthesis of renalse by the kidney and consequently reduced degradation of circulating norepinephrine. To verify this, we used a rat model of infarction-induced heart failure caused by ligation of the left anterior descending coronary artery. In these rats, renal expression of renalse, when measured at 4 weeks, was reduced, and this was associated with an increase in circulating norepinephrine.

**Conclusions** We conclude that impaired synthesis of renalse by the kidney may represent a novel mechanism underlying circulating norepinephrine accumulation in heart failure.

**ELECTROPHYSIOLOGICAL SUBSTRATE FOR CANINE ATRIUM**

DOI: 10.1136/hrt.2010.208967.182

Liu Ying, Yang Yanzong, Jiang Yirong, Xia Yunlong, Gao Lianjun, Yang Donghui, Li Shijun, Yin Xiaomeng, Lin Zhuh. The First Affiliated Hospital of Dalian Medical University, Dalian, China

**Objective** Hypertension is frequently complicated by atrial fibrillation (AF). However, the atrial substrate for AF is not known. This study investigated the electrophysiological properties of atrial repolarisation by monophasic action potential (MAP) in order to explore the mechanism of paroxysmal AF initiation and maintenance.

**Methods** MAP were recorded from left and right atrium in 14 canine action potential duration (APD) at 90% repolarisation (APD90). Repetitive atrial firing (RAF) and APD alternans (the difference in APD between two consecutive beats, were induced by overdrive pacing at LA and RA) were induced by use of programmed stimulation at LA and RA. In the study, episodes of RAF were recorded and analysed.

**Results** APD90 were significantly shorter in the left atrium compared to the right atrium ((157.4±43.5) vs (170.9±37.9), p<0.05). The mean S1S2 interval induced RAF was (150±32) ms. 15 RAF were induced in 14 dogs. RAF induced in LA were more than in RA (11 vs 5, p<0.05). Alternans of APD were induced at CL of (162±25) ms. 13 APD alternans were induced at LA (8) and RA (5) of 14 dogs. In total, 61 episodes of RAF were induced in 14 canines. 30 episodes of RAF were induced in the left atrium, more than in the right atrium (25, p<0.05). The incidence of RAF and alternans was significantly higher in LA than in RA. Heterogeneity between LA and RA repolarisation creates substrate for re-entrant arrhythmias and vulnerability to atrial fibrillation.

**Conclusions** BPA promotes arrhythmogenesis in female rat heart by induced DADs, and effects of BPA and E2 are synergistic instead of additive.

**Introduction** Although anoxic preconditioning (APC) in the myocardium has been investigated for many years, its physiological mechanism is still not completely understood. Increasing evidence indicates that transiently increased resistance to ischaemic damage following APC is dependent on de novo protein synthesis. However, the key effector pathway(s) associated with APC still remains unclear.

**Methods** We cloned a Linvin expression vector, transfected it into rat cardiomyocytes, and examined Linvin expression in rat cardiomyocytes that were subjected to A/R injury. Moreover, we studied the role of three major MAPK pathways, for example, p38 MAPK, JNK, and ERK1/2, in order to evaluate the molecular mechanism underlying Linvin up-regulation and A/R induced cardiomyocyte injury.

**Results** APC induced an up-regulation of Linvin and the transfection of Linvin gene into the cardiomyocytes attenuated A/R injury. The inhibition of p38 MAPK by SB203580 abolished both the Linvin up-regulation and the cardio-protection provided by APC.

**Conclusion** APC could act to protect the heart from A/R injury with cooperation from the Linvin in addition, it up-regulates Linvin expression through a p38 MAPK signalling pathway.

**THE PROTECTION EFFECTS OF TRIMETAZIDINE ON RATS MYOCARDIAL INFARCTION**

DOI: 10.1136/hrt.2010.208967.184

Yanting Luo, 1Jinlia Liu, 2Fei Chen, 2Wen Tan. 1Department of Cardiology, The Third Affiliated Hospital, Sun Yat-sen University, Guangzhou, China; 2Key-Pharma Biomedical Company, Dongguan, P. R. China

**Objective** To observe the myocardial protection effects of trimetazidine on Sprague-Dawley (SD) rats with myocardial infarctions (MI).

**Methods** 90 SD rats were randomly assigned to normal control group (NL, n=30), Trimetazidine group (T, n=30) and sham-operated group (MI, n=30). Trimetazidine group (T, n=30) and sham-operated group
