Background It is not known how survival has changed over time
for patients who do and do not receive an early invasive strategy
for the management of AMI.

Methods Accelerated failure-time and relative survival analyses of
583,466 patients recorded in the Myocardial Ischaemia National

Figure 1 Temporal trends in adjusted 6-month survival estimates stratified by age group
for (A) patients with STEMI who received emergency reperfusion therapy, (B) patients with

Figure 2 Temporal trends in adjusted 6-month survival estimates stratified by age group
for (A) patients with NSTEMI who received coronary angiography and (B) patients with

PCI percutaneous coronary intervention, AMI acute myocardial infarction, STEMI ST-elevation
myocardial infarction, NSTEMI non ST-elevation myocardial infarction.
Audit Project (MINAP) with AMI stratified by acute reperfusion treatment (thrombolysis or primary percutaneous coronary intervention (PPCI)) for STEMI and coronary angiography for NSTEMI.

**Results** Table 1 shows the patient characteristics by STEMI and NSTEMI phenotype. Figure 1 shows that survival improved significantly over time for STEMI patients who received acute reperfusion therapy (Time Ratio (TR) 1.47, 95% CI 1.22 to 2.78), and was stable for those who did not (TR 1.02, 95% CI 0.85 to 1.22). Whilst there were significant improvements in survival for NSTEMI patients who underwent coronary angiography (TR 1.39, 95% CI 1.18 to 1.62), there was a significant decline for those who did not (TR 0.70, 95% CI 0.65 to 0.75) (figure 2). Patients without acute reperfusion therapy or coronary angiography had a greater number of co-morbidities, but the use of secondary prevention medications were comparable to patients who received emergency reperfusion therapy or coronary angiography. There was a highly significant hospital-level survival effect, with lower crude mortality rates within hospitals with higher use of coronary angiography and PPCI.

**Conclusions** Survival to 6-months after AMI is high, and has improved. Whilst survival estimates for STEMI patients who did not receive emergency reperfusion were stable, it worsened for NSTEMI patients not receiving coronary angiography. Hospital treatments (including revascularisation), and their variation in use, are associated with longer-term survival.
